```

PCA on the lab genes -imputed

```
#select the genes and lab muce
lab <- hm %>%
    dplyr::filter(origin == "Lab", Position == "mLN") #selecting for mln to avoid
# duplicates
lab <- unique(lab)
gene <- lab %>%
    dplyr::select(c(Mouse_ID, all_of(Gene_lab)))
genes <- unique(gene)</pre>
```

```
genes <- genes[, -1]

#remove rows with only nas
genes <- genes[,colSums(is.na(genes))<nrow(genes)]

#remove colums with only nas
genes <- genes[rowSums(is.na(genes)) != ncol(genes), ]

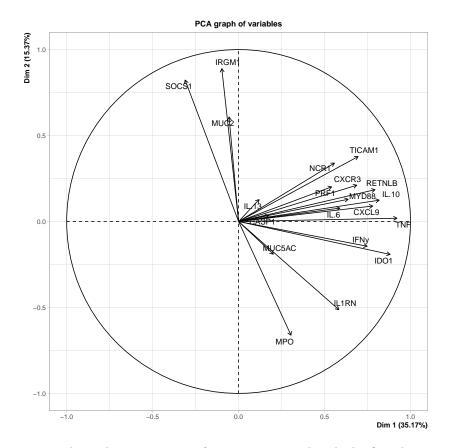

vis_dat(genes)</pre>
```

```
## Warning: 'gather_()' was deprecated in tidyr 1.2.0.
## i Please use 'gather()' instead.
## i The deprecated feature was likely used in the visdat package.
## Please report the issue at <a href="https://github.com/ropensci/visdat/issues">https://github.com/ropensci/visdat/issues</a>.
```

```
#select same rows in the first table
gene <- gene[row.names(genes), ]

# we can now run a normal pca on the complete data set
res.pca <- PCA(genes)</pre>
```

Caution: When imputing data, the percentages of inertia associated with the first dimensions will be overestimated.

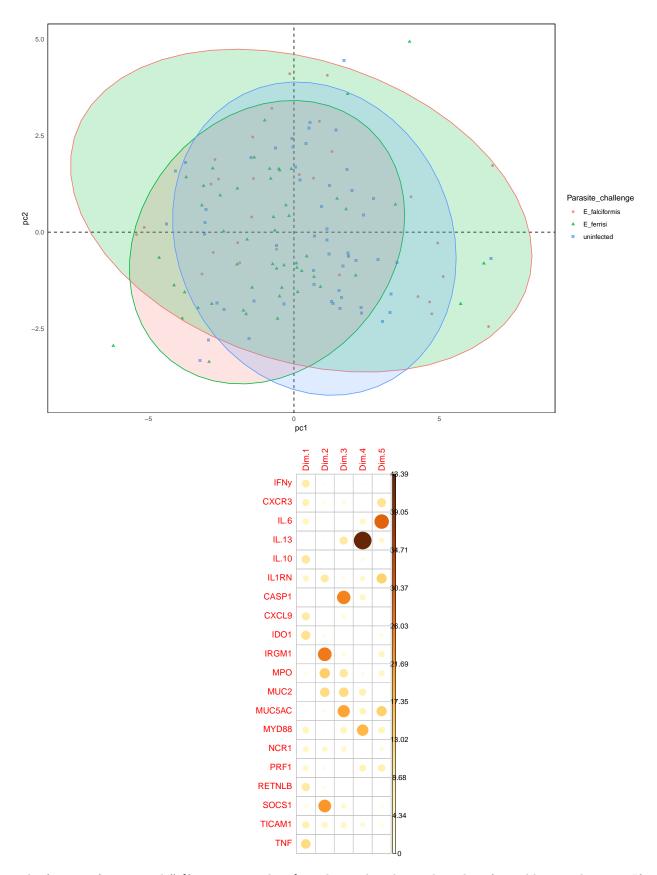

Another problem: the imputed data are, when the pca is performed considered like real observations. But they are estimations!!

Visualizing uncertainty due to issing data:

-> mulrimple imputation: generate several plausible values for each missing data point

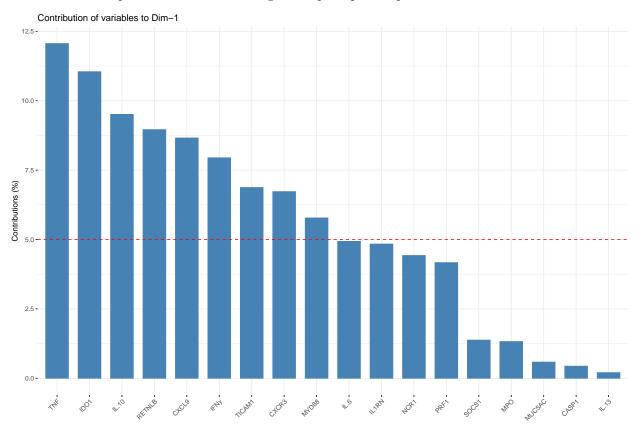

We here visualize the variability, that is uncertainty on the plane defined by two pca axes.

Biplot of the imputed gene pca

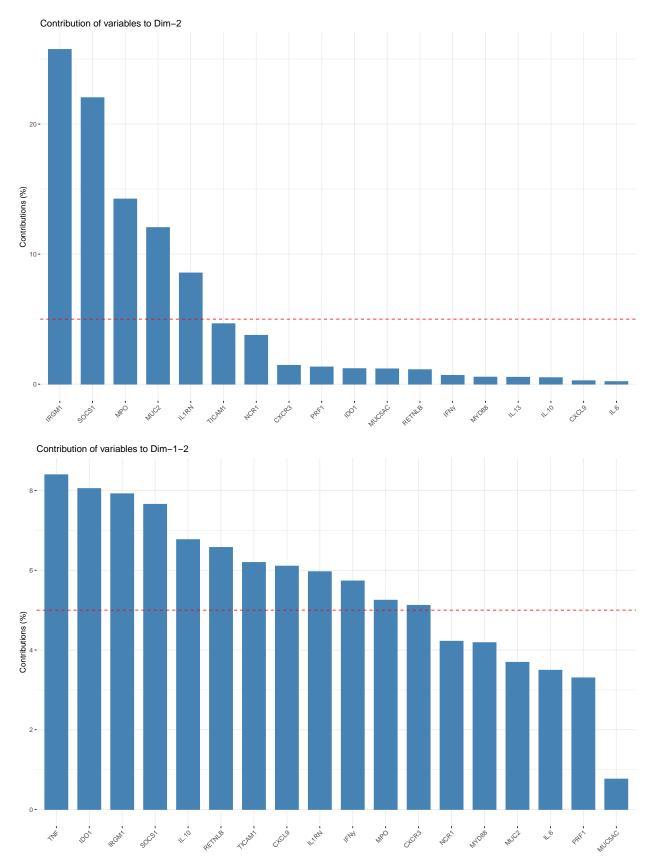

The function fviz_contrib() [factoextra package] can be used to draw a bar plot of variable contributions. If

your data contains many variables, you can decide to show only the top contributing variables. The R code below shows the top 10 variables contributing to the principal components:

Contributions of variables to PC2
fviz_contrib(res.pca, choice = "var", axes = 2, top = 18)

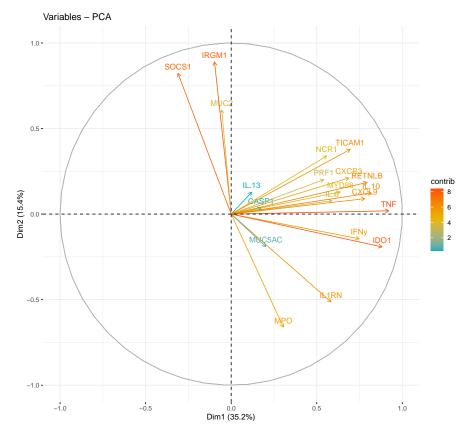

The red dashed line on the graph above indicates the expected average contribution. If the contribution of

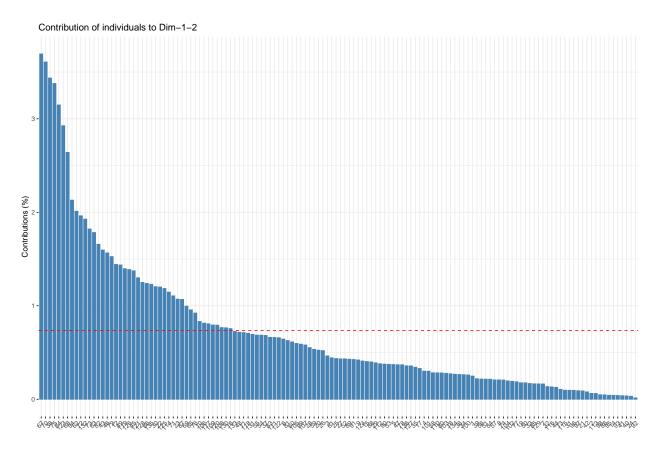

the variables were uniform, the expected value would be 1/length(variables) = 1/10 = 10%. For a given component, a variable with a contribution larger than this cutoff could be considered as important in contributing to the component.

Note that, the total contribution of a given variable, on explaining the variations retained by two principal components, say PC1 and PC2, is calculated as contrib = [(C1 * Eig1) + (C2 * Eig2)]/(Eig1 + Eig2), where

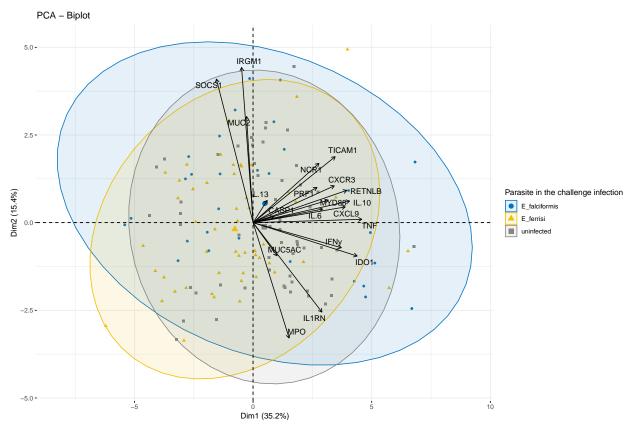

C1 and C2 are the contributions of the variable on PC1 and PC2, respectively Eig1 and Eig2 are the eigenvalues of PC1 and PC2, respectively. Recall that eigenvalues measure the amount of variation retained by each PC. In this case, the expected average contribution (cutoff) is calculated as follow: As mentioned above, if the contributions of the 10 variables were uniform, the expected average contribution on a given PC would be 1/10 = 10%. The expected average contribution of a variable for PC1 and PC2 is : [(10* Eig1) + (10 * Eig2)]/(Eig1 + Eig2)

To visualize the contribution of individuals to the first two principal components:

PCA + Biplot combination

In the following example, we want to color both individuals and variables by groups. The trick is to use pointshape = 21 for individual points. This particular point shape can be filled by a color using the argument fill.ind. The border line color of individual points is set to "black" using col.ind. To color variable by groups, the argument col.var will be used.

Linear models:

```
##

Try instead: LLR test (likelihood ration) (LM4 package)?
https://www.rdocumentation.org/packages/lmtest/versions/0.9-38/topics/lrtest
In this way you compare each model, with the different variables used to predict.
Another way is to compare the AIC. (function: step)
weight_lm3 <- lm(max_WL ~ pc1 + pc2 + hybrid_status, data = lab)</pre>
