GAPDH HKG

B-actin HKG

Ppia HKG

Ppip HKG

CDC42 HKG susceptible to DNA contamination

Housekeeping genes selected: GAPDH and PPIB

Relm-b mucosal defense factor (goblet cells)

Muc2 the major secretory mucin within the gastrointestinal tract

TFF3 mucosal defense factor (goblet cells)

Muc5ac similar to MUC2, produced by surface goblet cells

NKp46 NK marker

F4/80 macropalge marker (distinguish by immune response trend)

Mpo myeloperoxidase in Neutrophils

MyD88 TLR protein, NF-kB IRAK protein, inflammation marker by TLR MyD88-Dependent Pathway caspase-1 inflammasome marker (IL-1b and IL-18 production)

IL-1Ra natuaral IL-1b antagonist for infection control (if not increase in Tregs is seen)

CXCL9, immune cell migration marker + Th1 activator (confirm FACS)

CXCR3, CXCL9 and CXCL11 receptor

IL-6 TNF inhibitor,

IL-12ra T-cell marker Th1

IFN-y compare with IFN-y producing cells and IFN-y ELISAs, should correlate wit PRF1, NKp46 and F4/80. One of these cell types just have to be doing the job!

IRG6A autonomous cell defense (opsonization)

TNF-a upregulated in eimeria but not well explained. Could be present and driving infection where IFN-y isn't.

IL-17 in case IFN-y isn't coming up but pathogenicity is

TRIF Type I IFN production TRIF Dependent Pathway

Socs1 JAK/STAT signaling pathway, proinflammatory regulating + T-cell differentiation, could explain severity

IDO1 DC, monocyte and MC protein regulating T-cell activity

Prf1 perforin, should be dominant in primary infections, but must be correlated between T-cell and NK cell expresions

CD56 CD56bright = more cytokine producing NKs, CD56dim = more direct cytotoxic killing

IL-4

IL-13

IL-10

1. Gene expression in the laboratory infections - Heatmap

#document gene normalization https://www.youtube.com/watch?v=tgp4bbnj-ng paper: Licak Analysis of relative gene expression data using real time quantitative Add the normalized Gene expression to the rest of the data

https://www.youtube.com/watch?v=tgp4bbnj-ng

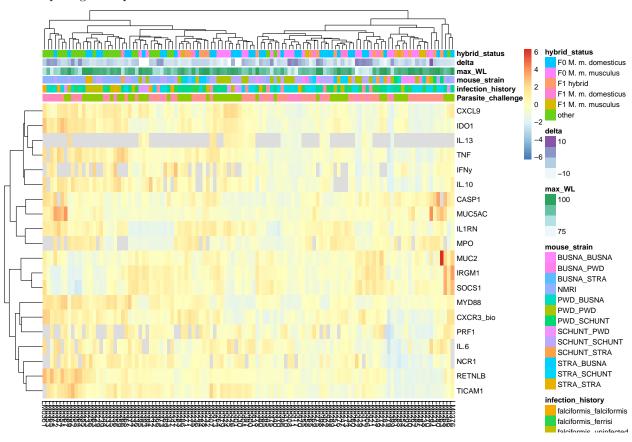

If you don't need a graph with absolute values of expressions and just relative comparison then you can choose one of the samples as a calibrator (control sample). This control sample will have the value of 1 and the rest of the samples will be compared relative to this one. I would choose as control the sample with the lowest expression.

https://www.researchgate.net/post/How-can-I-analyze-qPCR-data-without-control-sample

```
#create calibrator samples for the analysis
# create new columns with the minimum of each gene
# which I will use as the calibrator sample
#create a function which gives you the PPIB value for the minimum value of a gene
Dct_Calibrator <- function(x) {</pre>
h <- gene[which(gene[[x]] == min(gene[[x]], na.rm = TRUE)), ][,c(x, "PPIB")]
h[[x]] - h[["PPIB"]]
#Apply the function to all genes
Calibrator_values <- as.data.frame(unlist(lapply(Genes, Dct_Calibrator)))</pre>
Calibrator_values <- cbind(Calibrator_values, as.data.frame(Genes))</pre>

Heatmap on gene expression data:

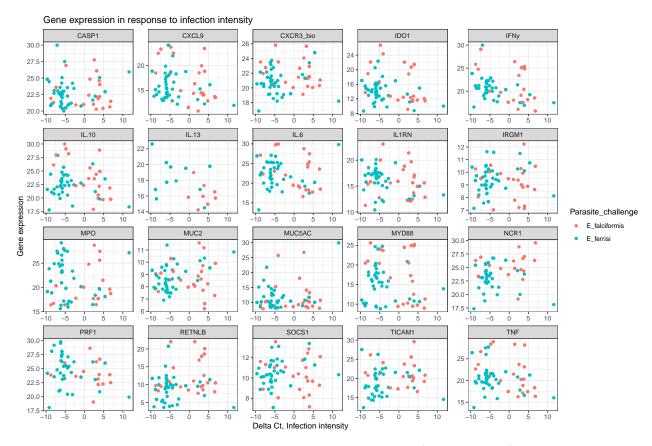

2. Correlations between the genes

Corrplot of correlations

Here is a corrplot of the correlations between the genes. I am using the non-normalized genes

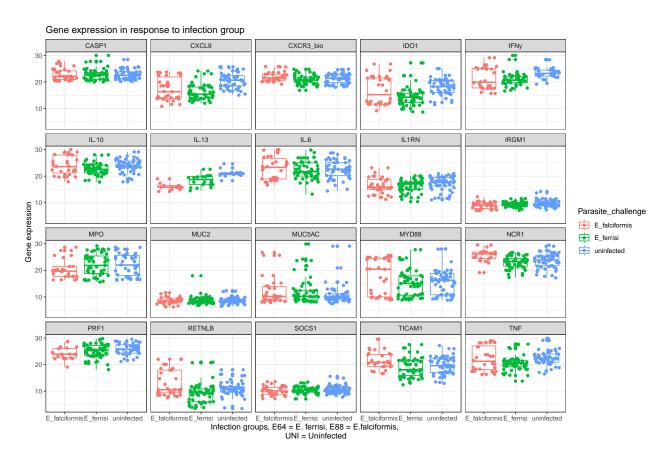

Warning: Removed 121 rows containing missing values (geom_point).

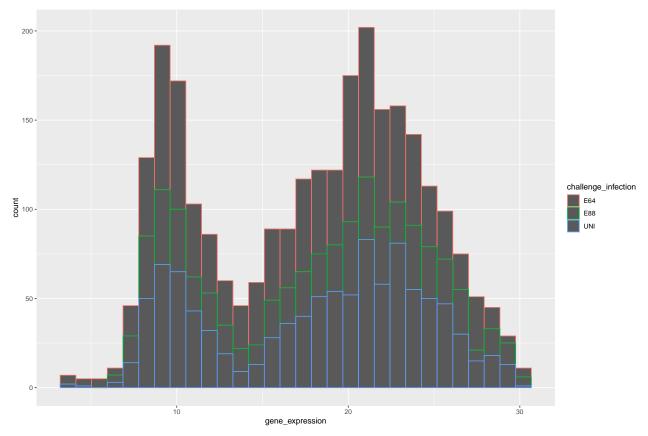

Warning: Removed 244 rows containing non-finite values (stat_boxplot).

Warning: Removed 244 rows containing missing values (geom_point).

Warning: Ignoring unknown parameters: echo

Warning: Removed 244 rows containing non-finite values (stat_bin).

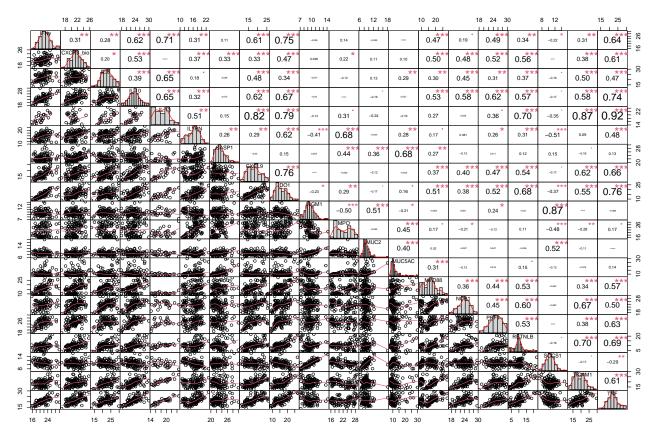

It is possible to compute a pca with missing data using the package missMDA. The missMDA package is dedicated to missing values in exploratory multivariate data analysis: single imputation/multiple imputation, etc.

Following the tutorial of the package author: Francois Husson: https://www.youtube.com/watch?v=OOM 8_FH6_8o

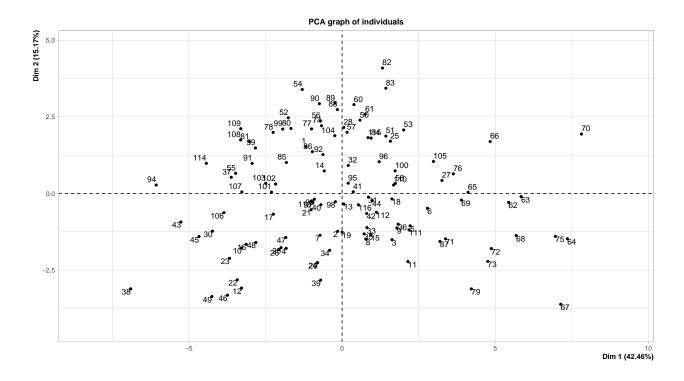

3. PCA

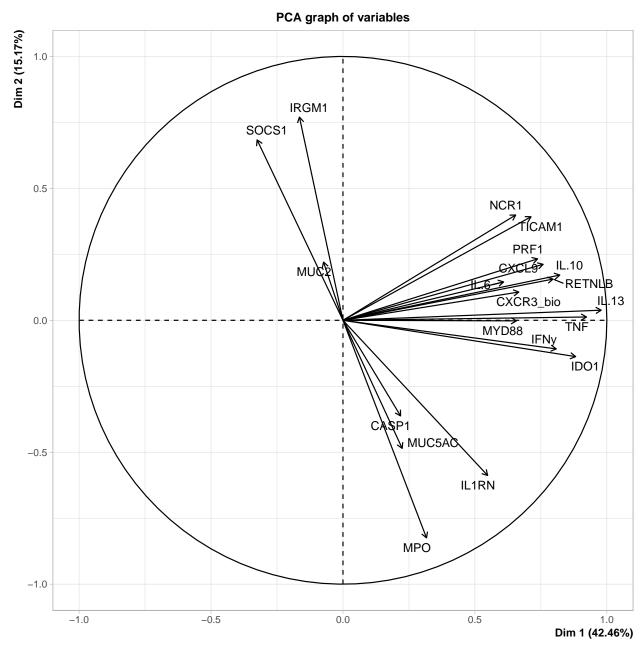

Handling missing data in a pca: Bad methods: removing individuals with missing data or replacing missing data with the mean (default setting in many packages).

We will now continue by using an iterative pca to impute missing data A. Initialization: impute using the mean B. Step lampda: # a. do pca on imputed data table S dimensions retained # b. missing data imputed using pca # c. means (and standard deviations) updated C. Iterate the estimation and imputation steps (until convergence) (convergence: the act of converging and especially moving toward union or uniformity)

Overfitting is a common problem due to believing too much in links between variables. -> regularized iterative PCA (This version is what is being implented in missMDA) This is a way of taking less risk when imputing the missing data. The algorithm estimates the missing data values with values that have no influence on the PCA results, i.e., no influence on the coordinates of the individals or variables.

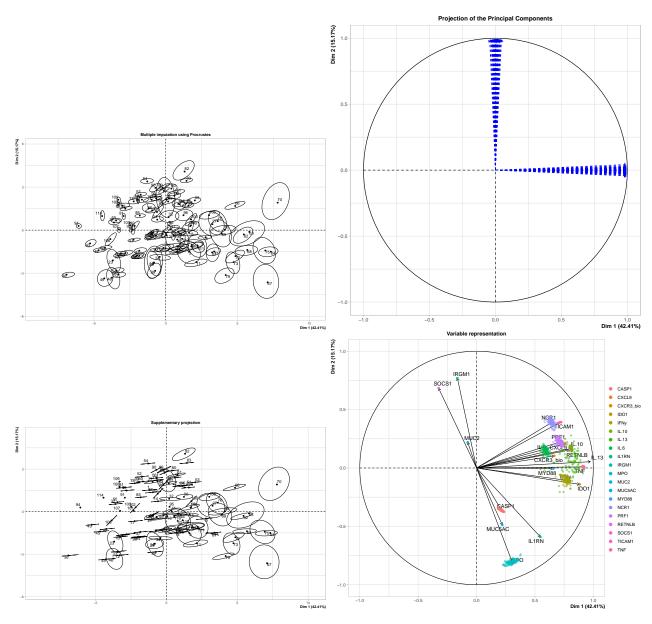

Caution: When imputing data, the percentages of inertia associated with the first dimensions will be overestimated.

Another problem: the imputed data are, when the pca is performed considered like real observations. But they are estimations!!

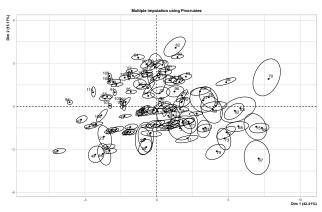

Visualizing uncertainty due to issing data:

-> mulrimple imputation: generate several plausible values for each missing data point

We here visualize the variability, that is uncertainty on the plane defined by two pca axes.

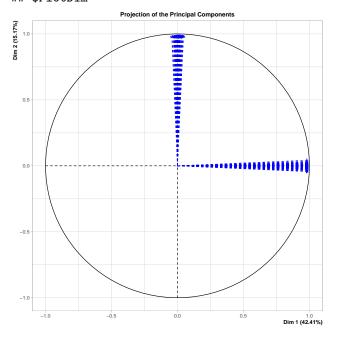

\$PlotIndProc

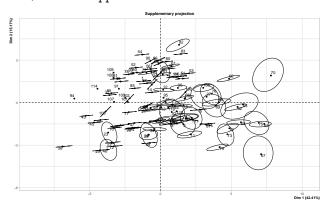

##

\$PlotDim

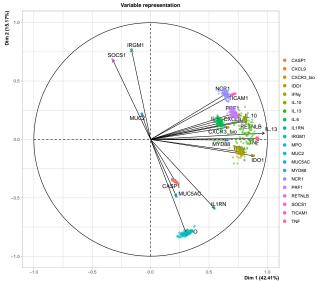

##

\$PlotIndSupp

##

\$PlotVar

but individuals that far away have many missing data. big ellipse = big uncertainty tight elipse (line) = low uncertainty

Variable representation: Poins tight together)look like one) - have no missing variables -> low uncertainty Points spread -> higher variability -> higher uncertainty

High uncertainty—> we should interpret the result with care

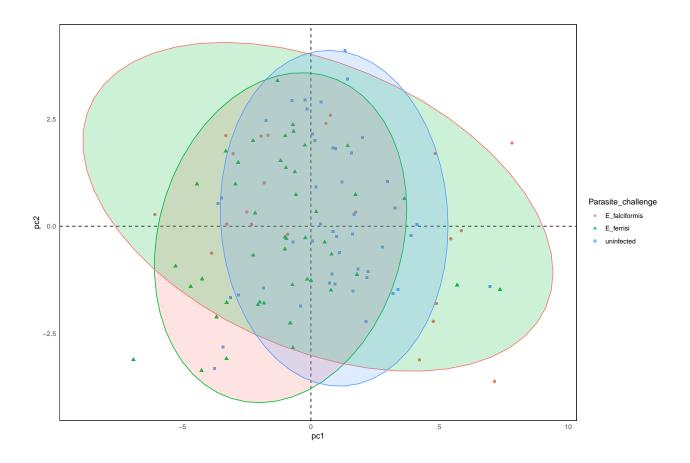

The individuals with many missing data values make the axes move, and thus the positions of all individuals

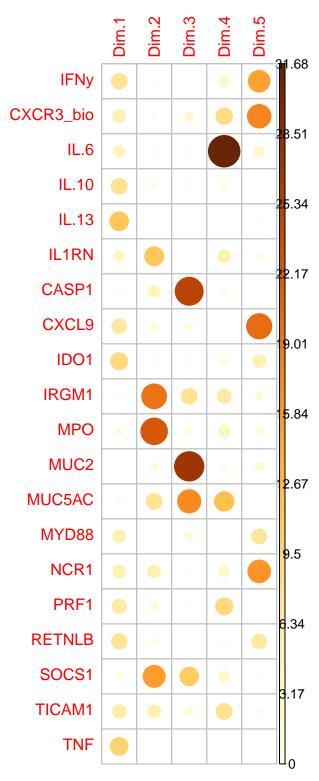

Therefore in the last plots every individual is getting an eclipse as they are as well influenced by the missing data of the others.

THe plot with the dimensions shows the projections of the pca dimensions of each imputed table on the pca plane obtained using the original imputed data table

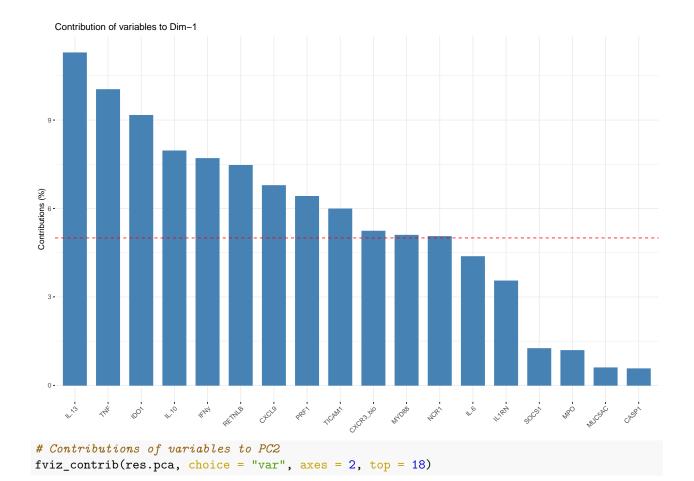

As all of the arrows are close to either the first or second axes, this means that the axes are stable with respect to the set of imputed tables -> we don't have evidence of instability here.

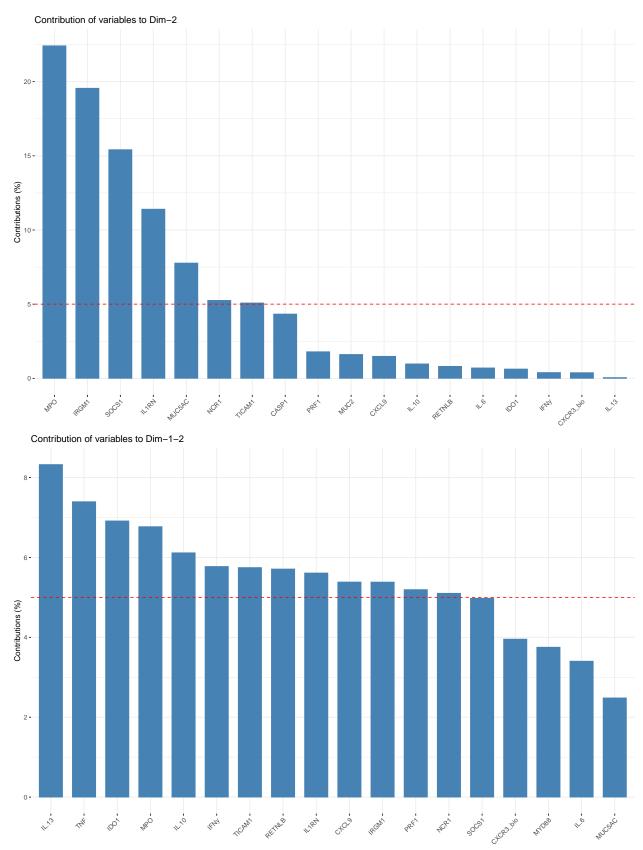

Biplot of the imputed gene pca

The function fviz_contrib() [factoextra package] can be used to draw a bar plot of variable contributions. If your data contains many variables, you can decide to show only the top contributing variables. The R code below shows the top 10 variables contributing to the principal components:

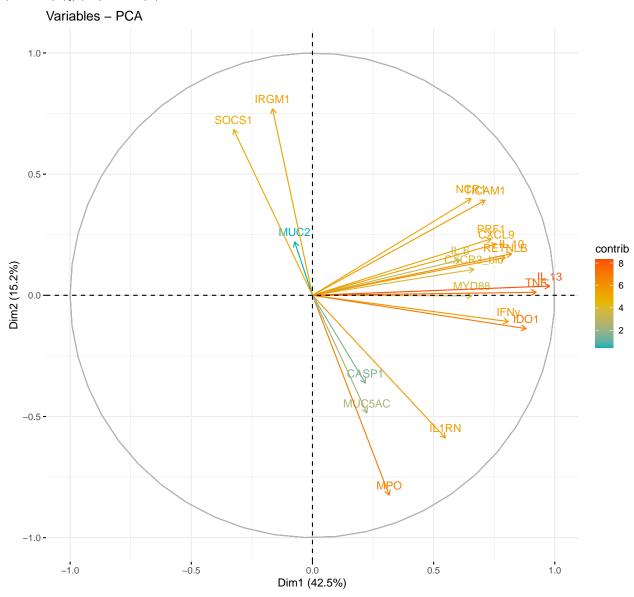

The red dashed line on the graph above indicates the expected average contribution. If the contribution of the variables were uniform, the expected value would be 1/length(variables) = 1/10 = 10%. For a given

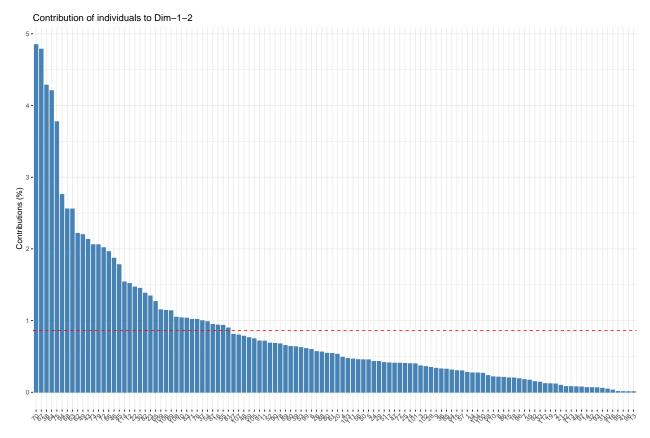

component, a variable with a contribution larger than this cutoff could be considered as important in contributing to the component.

Note that, the total contribution of a given variable, on explaining the variations retained by two principal components, say PC1 and PC2, is calculated as contrib = [(C1 * Eig1) + (C2 * Eig2)]/(Eig1 + Eig2), where

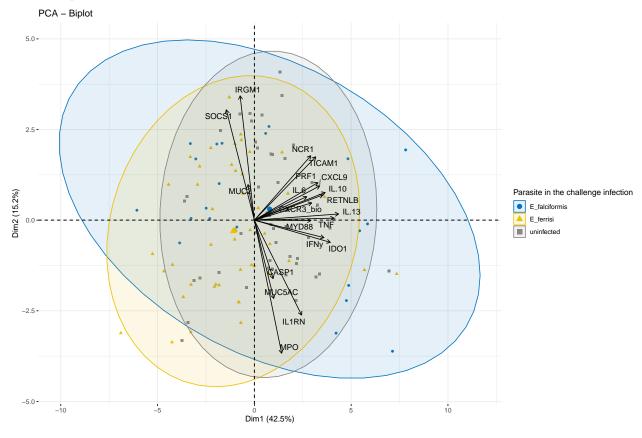

C1 and C2 are the contributions of the variable on PC1 and PC2, respectively Eig1 and Eig2 are the eigenvalues of PC1 and PC2, respectively. Recall that eigenvalues measure the amount of variation retained by each PC. In this case, the expected average contribution (cutoff) is calculated as follow: As mentioned above, if the contributions of the 10 variables were uniform, the expected average contribution on a given PC would be 1/10 = 10%. The expected average contribution of a variable for PC1 and PC2 is : [(10* Eig1) + (10* Eig2)]/(Eig1 + Eig2)

To visualize the contribution of individuals to the first two principal components:

PCA + Biplot combination

In the following example, we want to color both individuals and variables by groups. The trick is to use pointshape = 21 for individual points. This particular point shape can be filled by a color using the argument fill.ind. The border line color of individual points is set to "black" using col.ind. To color variable by groups, the argument col.var will be used.

Try instead: LLR test (likelihood ration) (LM4 package)?
https://www.rdocumentation.org/packages/lmtest/versions/0.9-38/topics/lrtest
In this way you compare each model, with the different variables used to predict.
Another way is to compare the AIC. (function: step)
weight_lm3 <- lm(max_WL ~ pc1 + pc2 + hybrid_status, data = imputed_expr)</pre>
weight_no_pc1 <- lm(max_WL ~ pc2 + hybrid_status, data = imputed_expr)</pre>

```

```
The Df column displays the degrees of freedom for the independent variable (the number of levels in the variable minus 1), and the degrees of freedom for the residuals (the total number of observations minus one and minus the number of levels in the independent variables). The Sum Sq column displays the sum of squares (a.k.a. the total variation between the group means and the overall mean). The Mean Sq column is the mean of the sum of squares, calculated by dividing the sum of squares by the degrees of freedom for each parameter. The F-value column is the test statistic from the F test. This is the mean square of each independent variable divided by the mean square of the residuals. The larger the F value, the more likely it is that the variation caused by the independent variable is real and not due to chance. The Pr(>F) column is the p-value of the F-statistic. This shows how likely it is that the F-value calculated from the test would have occurred if the null hypothesis of no difference among group means were true. The p-value of the fertilizer variable is low (p < 0.001), so it appears that the type of fertilizer used has a real impact on the final crop yield.
