#add an ending to the imputed columns
colnames(imp_field) <- paste(colnames(imp_field), "imp", sep = "_")</pre>
#now join it to the full data set of the laboratory infections
```

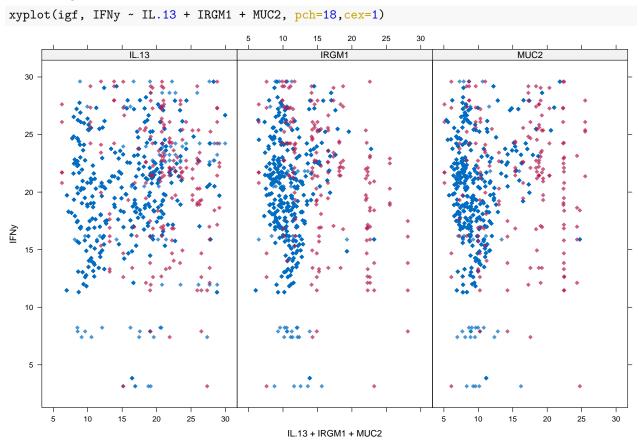

```
field_genes <- cbind(field_genes, imp_field)

Genes_wild_imp <- paste(Genes_wild, "imp", sep = "_")

field_genes <- field_genes %>%
   dplyr::select(c(Mouse_ID, all_of(Genes_wild_imp)))

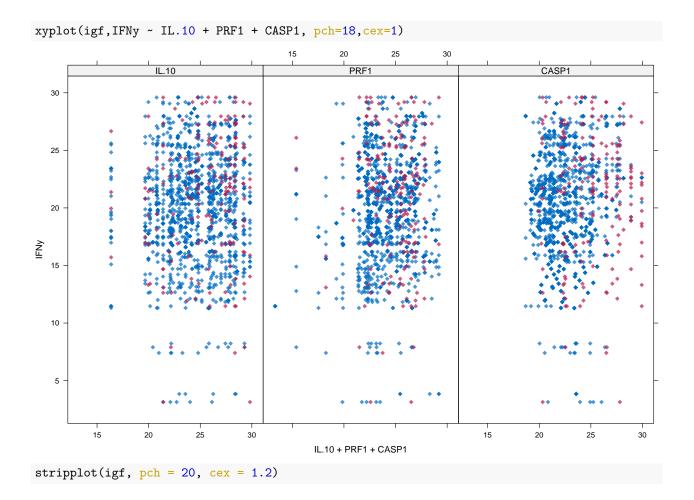

# join the now imputed columns to the field
field <- field %>%
   left_join(field_genes, by = "Mouse_ID")
```

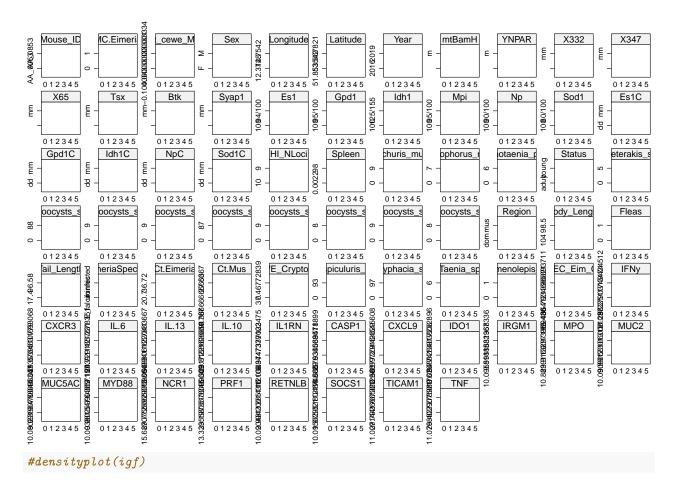

Let's compare the distributions of original and imputed data using a some useful plots. First of all we can use a scatterplot and plot Ozone against all the other variables. Let's first plot the variables for which we have few missing values.

What we would like to see is that the shape of the magenta points (imputed) matches the shape of the blue ones (observed). The matching shape tells us that the imputed values are indeed "plausible values".

Now let's plot the variables with many missing data points.

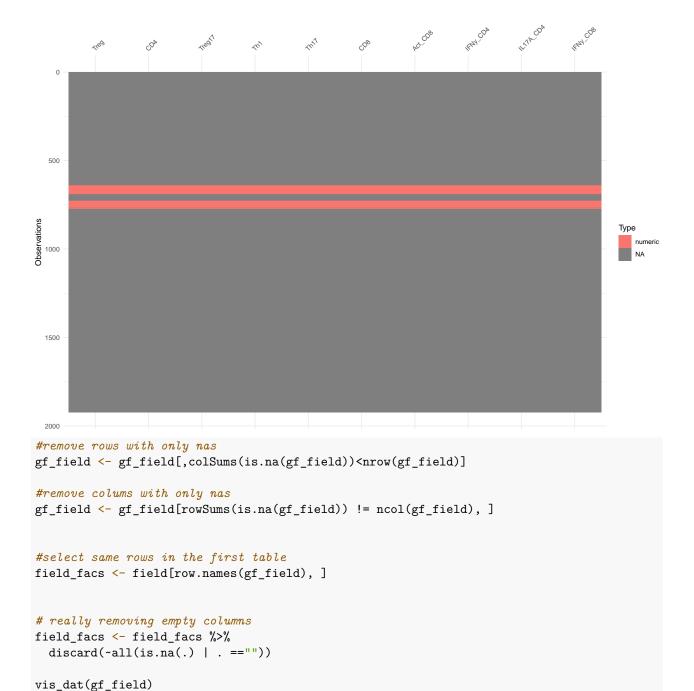

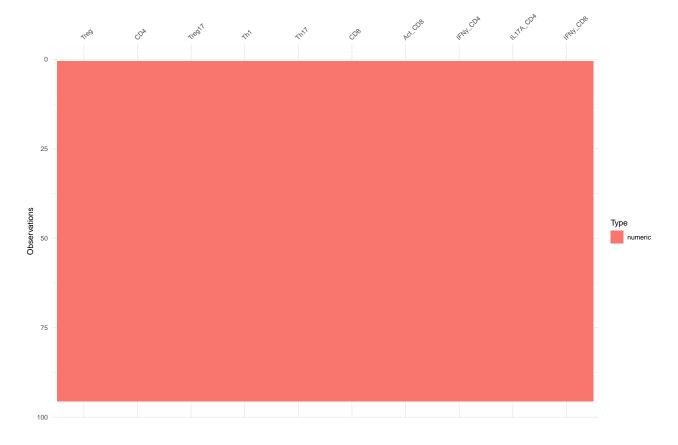

The density of the imputed data for each imputed dataset is showed in magenta while the density of the observed data is showed in blue. Again, under our previous assumptions we expect the distributions to be similar.

Another useful visual take on the distributions can be obtained using the stripplot() function that shows the distributions of the variables as individual points

#### **FACS**

```
gf_field <- field %>%
  dplyr::select(all_of(c(Facs_wild)))
vis_dat(gf_field)
```

We have no need to impute the facs data, as nothing is missing from the 95 samples

# Just add here the lab data and join the two tables

```
lab <- read.csv("output_data/Lab_imputed.csv")

# join the genes and facs data
imputed_mice <- lab %>%
  full_join(field, by = intersect(colnames(lab), colnames(field)))

##save the imputed data
write.csv(imputed_mice, "output_data/imputed_mice.csv", row.names = FALSE)
```
